Introduction

This lab aims to introduce the student with an interesting use case of a RaspberryPi, using the RaspberryPi as a Network Attached Storage device. At industrial or corporate sectors the NAS devices are very common since it provides means for transferring data fast and easily among different computers. Any user with the access to the network can use the data stored from any of their devices. However, cloud storage services and increasing speeds of the internet may cause a user to rethink about using a NAS device.

The microSD card storage or any attached USB storage device to the RaspberryPi can be converted to an NAS device this way. This document focuses on using the free space of the MicroSD card, if you plan to use a separate USB storage device such as an external hard drive, make sure you use a proper power supply for the RaspberryPi, which can supply sufficient amount of current for both devices.

We use SAMBA to setup the NAS in this lab. According to samba.org, SAMBA is,

Samba is the standard Windows interoperability suite of programs for Linux and Unix.

Since 1992, Samba has provided secure, stable and fast file and print services for all clients using the SMB/CIFS protocol, such as all versions of DOS and Windows, OS/2, Linux and many others.

This lab utilizes the **Local Area Network** created by the routers which many households use to access the internet. The RPi can be connected to the network via WiFi or Ethernet interfaces. Once setup you can leave the samba server running on background, the RaspberryPi can be used for your other applications. You will be able to use the NAS as any of the storage devices attached to your computer or the smart phone.

Outcomes

- Explore and practice different linux shell commands used for setting up packages, editing files etc.
- Exposure to one of the many extremely useful applications of RaspberryPi.

What you will need

- RaspberryPi
- Consumer grade router(A typical router provided by ISPs)

Implementation

*This lab utilizes the pre-set hostname **raspberrypi** of the RaspberryPi 3b+ of the Raspian OS. If you have setup a different operating system, you may need to find the assigned IP address for the RPi by your router, or assign a hostname. It is left as an exercise. In case you are unable to access using the **raspberrypi** hostname you will have to use the IP address of your RPi.*

Installing SAMBA

To install SAMBA package run the following commands.

```
sudo apt-get update
sudo apt-get upgrade
sudo apt-get install samba samba-common-bin
```

- Why did we use the **sudo** at the beginning of each command?
- Read more about the **apt** Advanced Package Tool.

Create a directory to be shared

In this step we strongly recommend you to use the terminal or the SSH terminal commands **cd**, **mkdir**. Make a note of the path of the folder you created. For example

```
/home/pi/shared
```

Creating a user account

In this lab you will implement an authenticated access NAS device.

For authenticated access, a user account needs to be created. This is essential because in the next step the user account needs to be allocated to a **group**. The default root user **pi** should not be used.

```
useradd -s /sbin/nologin netuser
```

Now to enable the account run,

```
passwd netuser
```

You can use username and password combination of your choice.

Now the user needs to be added to the **samba** database.

```
smbpasswd -a netuser
```

Create a Local Group

The user we just created needs to be added to a group in order to work with the samba server. It is highly recommended to use a separate group.

```
groupadd samba
```

Next we add our user `netuser` to the group `samba`.

```
usermod -aG samba netuser
```

Configuring permissions for the shared folder

The separate user and the group must be given the permission to access the folder we plan to use as the NAS.

```
chgrp -R samba /home/pi/shared/  
chmod 2770 /home/pi/shared/
```

Configure smb.conf file

SAMBA uses the `smb.conf` located in `/etc/samba`.

Use `nano` editor to edit the file. This is a text editor implemented on the command line interface itself.

Hint

You may need to explicitly use Super User access.

Under `[global]` section make sure these lines are inserted.

```
[global]  
    log file = /var/log/samba/%m  
    log level = 1  
    server role = standalone server  
    workgroup = WORKGROUP  
    map to guest = bad user
```

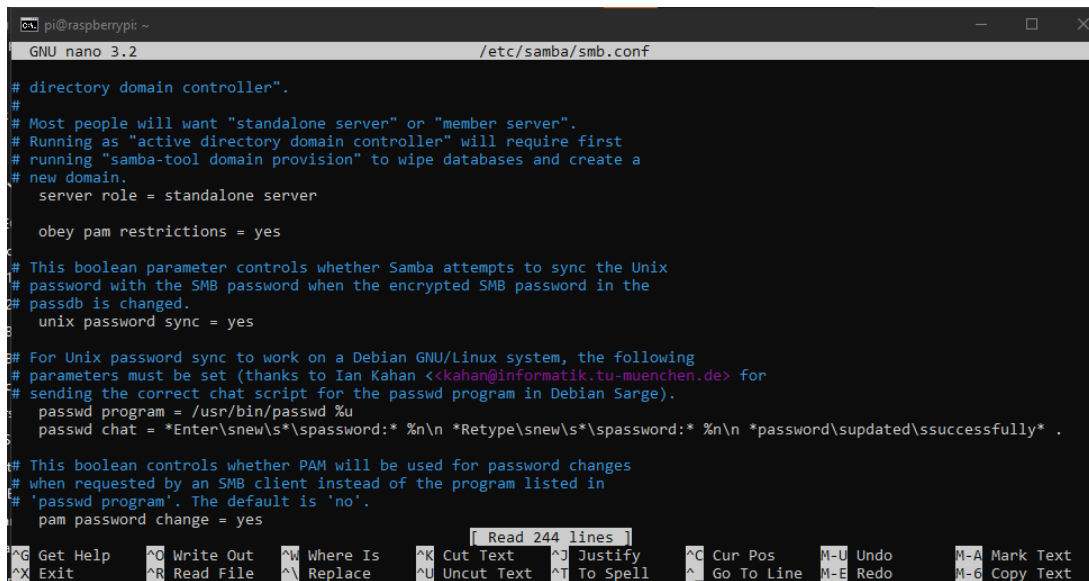

Scroll down to the end of the file, insert the following.

```
[NETWORK_SHARE]  
    # This share requires authentication to access  
    path = /home/pi/shared/  
    read only = no  
    valid users = @samba  
    inherit permissions = yes
```

The [NETWORK_SHARE] determines the display name of the shared folder on network. You can use any preferred name.

Under valid users you need to specify the group you created in previous steps.

The workgroup must be same as your Windows workgroup. The default is WORKGROUP, unless you have changed it in windows settings.

```
pi@raspberrypi: ~
GNU nano 3.2 /etc/samba/smb.conf

# directory domain controller".
#
# Most people will want "standalone server" or "member server".
# Running as "active directory domain controller" will require first
# running "samba-tool domain provision" to wipe databases and create a
# new domain.
server role = standalone server

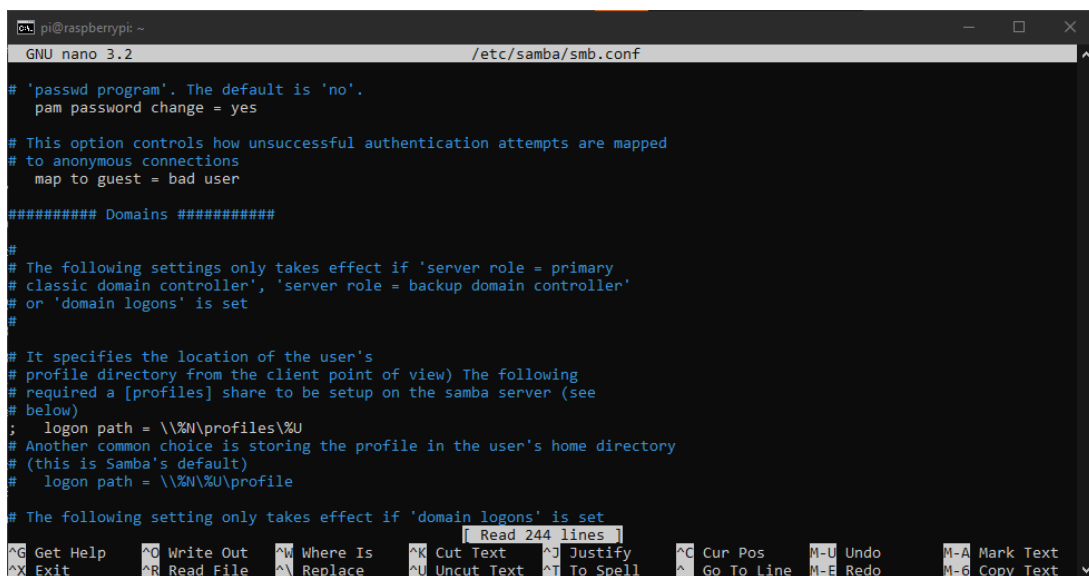

obey pam restrictions = yes

# This boolean parameter controls whether Samba attempts to sync the Unix
# password with the SMB password when the encrypted SMB password in the
# passdb is changed.
unix password sync = yes

# For Unix password sync to work on a Debian GNU/Linux system, the following
# parameters must be set (thanks to Ian Kahan <kahan@informatik.tu-muenchen.de> for
# sending the correct chat script for the passwd program in Debian Sarge).
passwd program = /usr/bin/passwd %u
passwd chat = *Enter\snew\s*\spassword:* %n\n *Retype\snew\s*\spassword:* %n\n *password\supdated\ssuccessfully* .

# This boolean controls whether PAM will be used for password changes
# when requested by an SMB client instead of the program listed in
# 'passwd program'. The default is 'no'.
pam password change = yes

```
pi@raspberrypi: ~
GNU nano 3.2 /etc/samba/smb.conf

# 'passwd program'. The default is 'no'.
pam password change = yes

# This option controls how unsuccessful authentication attempts are mapped
# to anonymous connections
map to guest = bad user

##### Domains #####

#
# The following settings only takes effect if 'server role = primary
# classic domain controller', 'server role = backup domain controller'
# or 'domain logons' is set
#
# It specifies the location of the user's
# profile directory from the client point of view) The following
# required a [profiles] share to be setup on the samba server (see
# below)
; logon path = \\%N\profiles\%U
# Another common choice is storing the profile in the user's home directory
# (this is Samba's default)
# logon path = \\%N\%U\profile

# The following setting only takes effect if 'domain logons' is set

```

Accessing the NAS from Windows 10

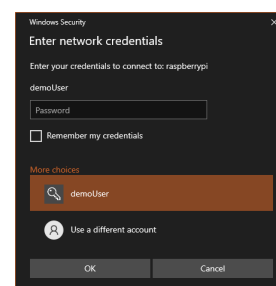

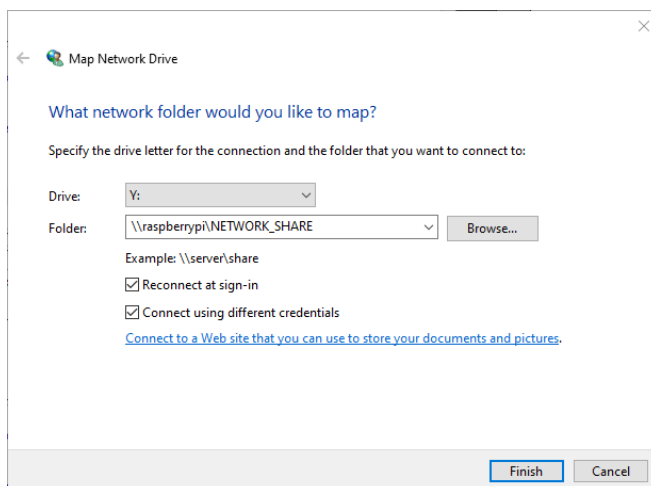

You will be mapping a new network drive to your computer.

Right click on This PC on Windows explorer and select **Map network drive**. A wizard will pop up.

Enter `\\raspberrypi\NETWORK_SHARE`. (Use the IP address in case you've changed the operating system).

Make sure to check **Connect using different credentials** checkbox.

In the next dialog box if there is a username already filled in click on more options and select **Use a different account**

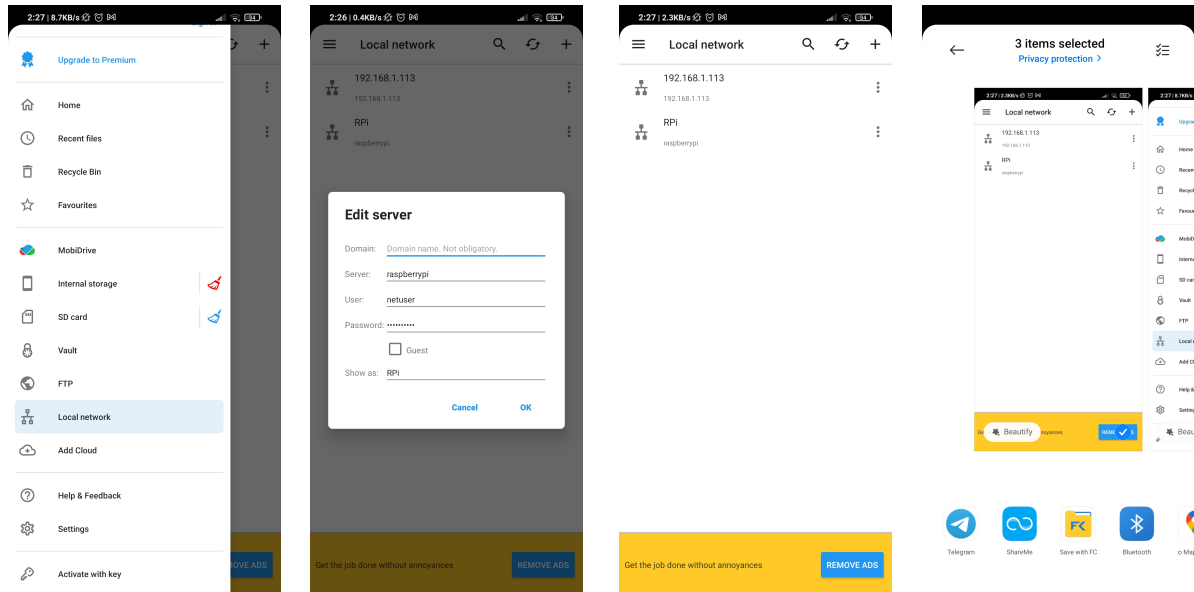

Accessing the NAS from Android

Many File Explorer apps support **samba**. The following steps are for the **File Commander** application. It has an *Ad supported* free version.

Other applications will follow a very similar procedure.

Once setup you can use *Save with FC* option under android share options to use the NAS just as a normal storage on your device.

Speed considerations

- The RaspberryPi 3B+ shares its USB controller with the Ethernet interface. In which scenarios will it affect the speed of the NAS?
- Use an application such as LAN speed test
- Are you using a free WiFi channel? You can use an Android app such as WiFi Analyzer
- If you have the free spectrum using 40MHz bandwidth channels will increase the maximum theoretical speed of your WiFi connection.
